I. System Load:

A. CPU load

1. ECU 1 CPU load:

ECU 1 Hyper Period:

To define the hyper-period LCM for all tasks periodicities is calculated

Task	Speed	Light	Door	bus sender
Periodicity	5ms	20ms	10ms	5ms

Then the Hyperperiod is equal to 20 ms

ECU 1 Load:

Tasks execution time is needed to calculate the load so assuming execution time based on previous project "EDF implementation" which uses less powerful MCU "LPC2129 compared to TM4C123"

Task	Speed	Light	Door	bus sender
Execution time	$20\mu s$	20μs	20μs	100μs

Then to calculate the CPU load:

Task	Execution	Periodicity	# Of tasks	Total execution
			per 20ms	time in 20ms
Bus Sender	0.1ms	5ms	4	$0.1 \times 4 = 0.4ms$
Speed monitor	0.02ms	5ms	4	$0.02 \times 4 = 0.08ms$
Door monitor	0.02ms	10ms	2	$0.02 \times 2 = 0.04ms$
Light monitor	0.02ms	20ms	1	$0.02 \times 1 = 0.02ms$

Then total utilization time = (0.4 + 0.08 + 0.04 + 0.02) = 0.54ms

For the CPU load in the Hyperperiod = $\frac{0.54}{20} \times 100\% = 2.7\%$

2. ECU 2 CPU Load:

ECU 2 Hyper Period:

To define the hyper-period LCM for all tasks periodicities is calculated

Task	Bus Receiver	Buzzer	Light
Periodicity	5ms	10ms	20ms

Then the Hyperperiod is equal to 20ms

ECU 2 Load:

Task	Bus Receiver	Buzzer	Light
Execution time	120μs	40μs	40μs

The execution time is increased to cover semaphore usage.

Then to calculate the CPU load:

			I -	
Task	Execution	Periodicity	# Of tasks	Total execution
			per 20ms	time in 20ms
Bus Sender	0.12ms	5ms	4	$0.12 \times 4 = 0.48ms$
Buzzer	0.04ms	10ms	2	$0.02 \times 4 = 0.08ms$
Light	0.04ms	20ms	1	$0.04 \times 1 = 0.02ms$

Then total utilization time = (0.48 + 0.08 + 0.04) = 0.60ms

For the CPU load in the Hyperperiod = $\frac{0.60}{20} \times 100\% = 3\%$

B. CAN Bus Load:

1. Messages Length & periodicity:

The CAN Frame consist of frame structure + Data, and for 11-bit message identifier the frame length 44 bit for zero data length message, also there is 3 bits which is for interframes space → the for can frame length = 44 + data-length + 3

Speed		
Variable length: 32bit		
CAN bus Frame Length = 44 + 32 +3 = 79 bit		
Frame periodicity: 5ms		
Total frames in 1 second =1000/5 = 200 frame		
Total Bits per 1 second = 200 * 79 = 15800 bit/sec		

Door		
Variable length: 8bit		
CAN bus Frame Length = 44 + 8 +3 = 55 bit		
Frame periodicity: 10ms		
Total frames in 1 second =1000/10 = 1 00 frame		
Total Bits per 1 second = 200 * 79 = 5500 bit/sec		

Light		
Variable length: 8bit		
CAN bus Frame Length = 44 + 8 +3 = 55 bit		
Frame periodicity: 2 0ms		
Total frames in 1 second =1000/10 = 50 frame		
Total Bits per 1 second = 200 * 79 = 2750 bit/sec		

2. Load Calculation:

Then the total bits sent in 1 secund = 15800 + 5500 +2750 = 24050 Bit

For 250Kbps bus bit rate:
$$Load = \frac{1}{250,000} \times 24050 \times 100 = 9.62\%$$

For 500Kbps bus bit rate:

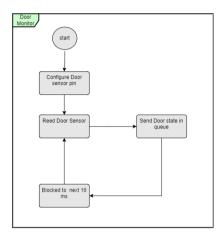

$$Load = \frac{1}{500,000} \times 24050 \times 100 = 4.81\%$$

For 1Mbps bus bit rate:

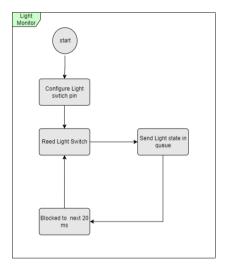

$$Load = \frac{1}{1000,000} \times 24050 \times 100 = 2.4\%$$
